

APPENDIX C – CRASH ANALYSIS METHODOLOGY AND RESULTS

Criteria for Evaluating Crash Experience

This crash analysis was conducted as part of the Operational Needs Assessment and includes a crash analysis for the freeway mainline, ramp merge and diverge points and ramp terminal intersections. The objectives are to calculate crash rates and severity rates, identify trends in crashes corridor wide, and pinpoint locations with the highest crash problems in the corridor.

WisDOT catalogs all crashes on state highways in a database that is updated several times throughout the year. The crash data was collected for every crash in the project limits of the WIS 441 corridor. The data was collected from WisDOT, the University of Wisconsin-Madison Traffic Operations and Safety Laboratory (TOPS) Laboratory, and the City of Appleton. Strand Associates Inc. provided crash data along the US41 corridor as part of their effort in the US 41 Interstate Conversion Project. That data was entered into a Geographic Information System (GIS) database for graphical representation. All deer related crashes were removed from the database prior to analysis due to the random occurrence of deer related crashes.

Every crash on the GIS map is shown on the freeway mainline even if it occurred on an interchange ramp. The crash location was estimated from the information contained in the crash databases. The following fields were used to estimate the crash locations:

- Initial direction
- Reference point number
- Reference point distance
- Crash type
- Accident location (intersection or non-intersection)
- Location on roadway

In general, the crash analysis was conducted on two primary sources of traffic crashes:

- Freeway Mainline Crashes
- Interchange Area Crashes

Freeway Mainline Crashes

Crash rates for WIS 441 and US 41 (Breezewood Lane to CTH U, County Line Road) were reported. This data was used to identify any trends by direction for the mainline highway. For evaluation and comparison purposes, an average annual crash rate was used as the basis for the rating criteria. The crash rates were determined from data obtained by the UW-Madison TOPS Lab (**Table 1**).

Table 1: WI Average Annual Crash Rates

RURAL INTERSTATE			
	Total	Fatal	Injury
2002	46	0.4	14
2003	55	0.6	17
2004	61	0.6	19
2005	67	0.6	20
2006	53	0.4	16

rates expressed as HMVMT

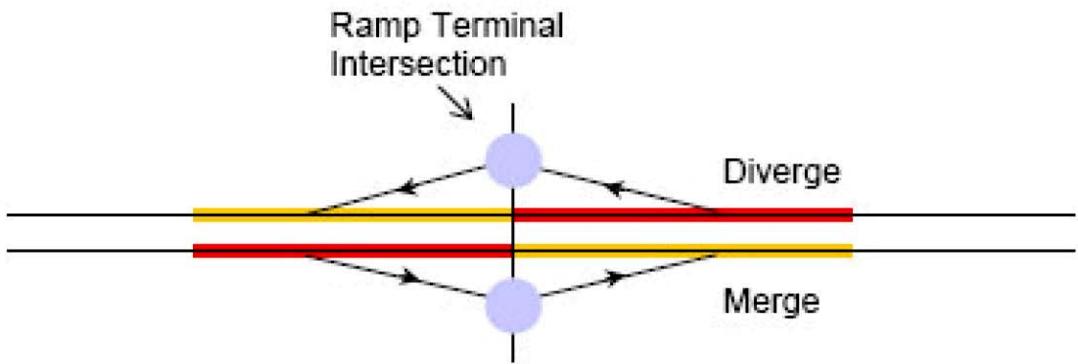

The average statewide rate for a rural interstate highway between 2002 and 2006 is 56 crashes per hundred-million vehicle miles traveled (HMVMT). This figure, again, excludes deer related crashes. This average crash rate is also used for comparison with the merge and diverge crashes.

Interchange Area Crashes

The study team calculated crash rates for all merge, diverge and ramp termini locations. Crashes for each merge and diverge location were determined based on a defined influence area along the ramp and mainline. The influence areas are defined below for each type of ramp.

For diamond ramps:

- The diverge influence area begins 1500' upstream of the diverge gore and ends 1500' downstream of the gore. The diverge influence area does not include any crashes on the ramp.
- The merge influence area begins 1500' upstream of the merge gore point and ends 1500' downstream of the merge gore point. It also includes half of the on-ramp.
- The diverge and merge influence areas should end at the crossroad bridge if there is less than 3000' between the diverge and merge gore points.
- The interchange termini influence area begins at the diverge gore and extends the entire length of the off-ramp and half-way up the on-ramp. The influence area should also include 1500' upstream and downstream of the ramp terminal intersection on the crossroad. If there is less than 1500' between the ramp intersections and the next intersection on the crossroad, the termini area should end at the midpoint between the intersections.
- If there is less than 3000' between adjacent interchanges, the upstream merge area and the downstream diverge area should start at the midpoint between the two interchanges.

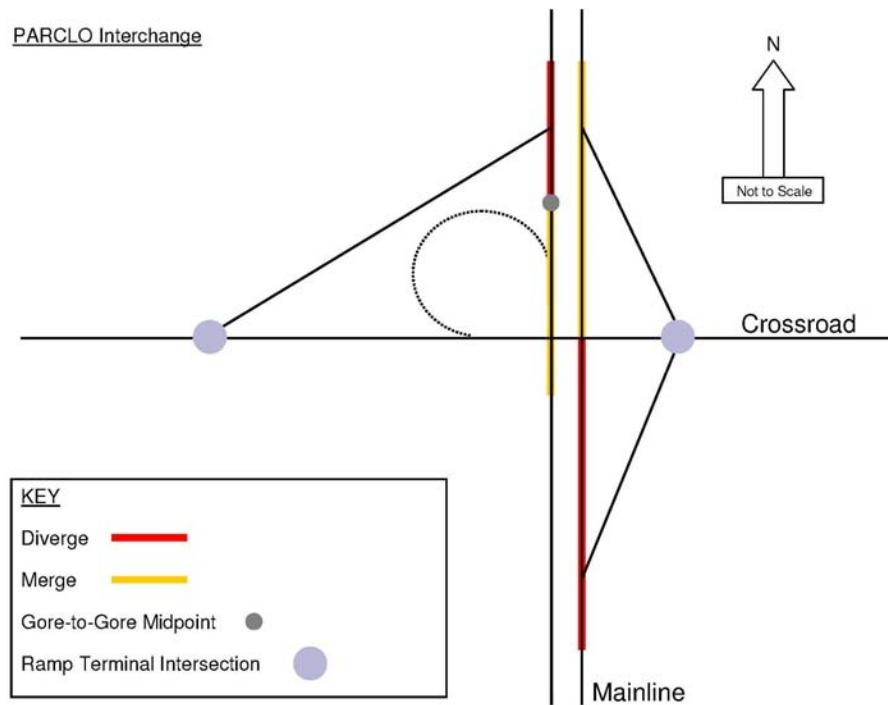

For double loop ramps:

- The diverge influence area begins either 1500' upstream of the diverge gore point or at the midpoint between the upstream merge gore point and the diverge gore point, whichever is shorter, and ends 1500' downstream of the diverge gore point. The diverge influence area does not include any crashes on the ramp.
- The merge influence area begins 1500' upstream of the merge gore point and ends either 1500' downstream of the merge gore point or at the midpoint between the merge gore point and the downstream diverge point, whichever is shorter. The merge influence area does not include any crashes on the ramp.
- The interchange termini influence area begins at the diverge gore and extends the entire length of the off-ramp and corresponding on-ramp. On the cross street, crashes occurring between ramp terminals were assigned to the nearest intersection.

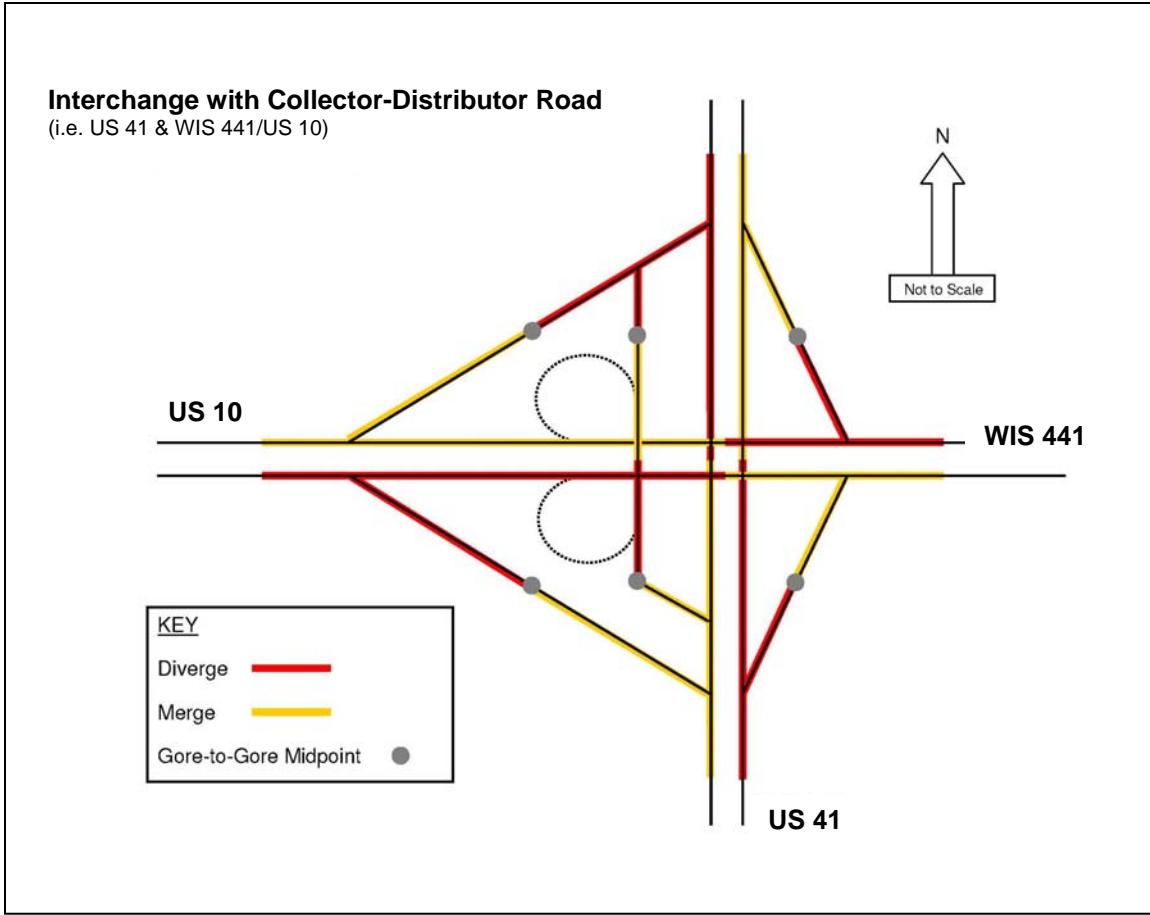

For partial cloverleaf interchanges:

- The diverge influence area begins 1500' upstream of the diverge gore point and ends either 1500' downstream of the diverge gore point or the midpoint between the diverge gore point and the downstream merge gore point, whichever is shorter. The diverge influence area does not include any crashes on the ramp.
- The merge influence area begins either 1500' upstream of the merge gore point or the midpoint between the upstream diverge gore point and the merge gore point, whichever is shorter, and ends 1500' downstream of the merge gore point. The merge influence area does not include any crashes on the ramp.
- The interchange termini influence area begins at the diverge gore point and extends the entire length of the off-ramp and corresponding on-ramp. On the cross street, crashes occurring between ramp terminals were assigned to the nearest intersection.

For interchanges with collector-distributor roads:

- The diagram following diagram provides a graphical representation of the merge and diverge areas classified on interchanges with collector-distributor road systems. The methodology incorporates a combination of the procedures used for both diamond and loop ramp configurations.

After the crashes were separated into influence areas, they were further separated by year (2002-2006) and by severity (property damage only, injury or fatality). The team then calculated the annual crash rates, and from those calculated the annual severity rates using the following formula:

$$\text{Severity_Rate} = \frac{\text{injury_crashes} + \text{fatal_crashes}}{\text{total_crashes}}$$

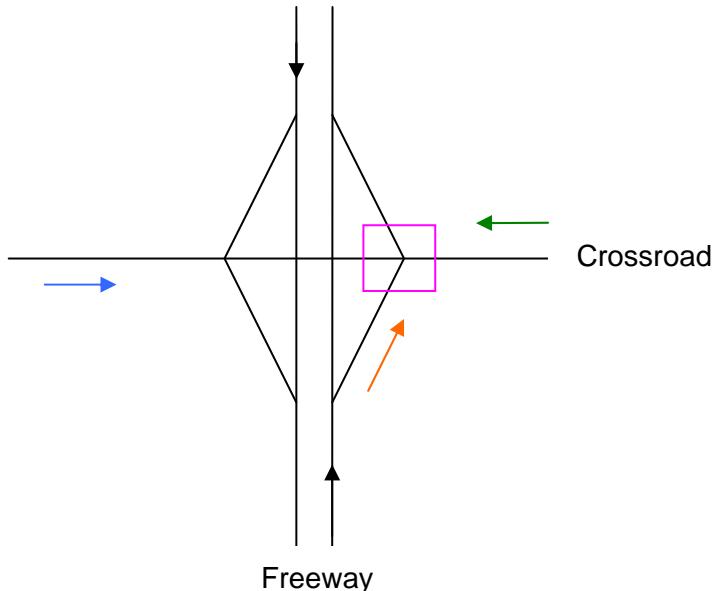

The higher the severity rate, the more hazardous the study location is to the safety of the drivers. A low severity rate indicates that the majority of the crashes involve property damage and little to no injuries to the drivers. If over half of the crashes at a specific location are severe, a severity rating of greater than 0.5, it is a strong indicator that the area has deficiencies that contribute to the poor rating.

The annual crash rates and a five-year average crash rate were calculated for each interchange. Approaching traffic volumes were obtained using existing annual average daily traffic (AADT) counts for the mainline. The intersections incorporated existing AADT values along with turning movement counts. Approaching traffic volumes were calculated using the following methods:

- Mainline:
 - Entering traffic for diverge = existing AADT for the segment approaching the interchange.
 - Entering traffic for merge = existing AADT for the segment approaching the interchange minus the AADT exiting on the off-ramp in the same direction.
- Intersections:
 - For cross road intersections, all four approaches were added and used as the existing AADT
 - For intersections at ramp terminals, see below

Referring to the figure below

- The analyzed intersection is the pink box
- This intersection has AADT's from each approach therefore not giving one value for each intersection
- The one-way entering AADT's were added from each entering approach to the ramp terminal to determine the overall intersection AADT
- Two assumptions were made in the determination of entering traffic volumes:
 1. If two way AADT values were provided, a 50/50 bi-directional split was used
 2. At the adjacent ramp terminal, the total entering traffic from the off-ramp equals the total existing traffic to the on-ramp.
- Based on these assumptions, the total entering AADT = green arrow + orange arrow + blue arrow

Annual crash rates were calculated using the following formulas:

- Merge and diverge sections:

$$\text{Annual Crash Rate} = \frac{100,000,000 * C}{365 * n * V * L}$$

Units represent the number of crashes per 100 million vehicle miles traveled (HMVMT)

Where C = number of crashes in analysis years

n = number of analysis years

V = AADT (vpd)

L = influence area of roadway section (miles)

- Ramp terminal intersections:

$$\text{Annual Crash Rate} = \frac{1,000,000 * C}{365 * n * V}$$

Units represent the number of crashes per one million entering vehicles (MEV)

Where: C = number of crashes in analysis years

n = number of analysis years

V = AADT (vpd)

Wisconsin statewide averages for urban intersections from a recent Wisconsin TOPS study were also used to establish rating criteria for the ramp terminal intersections. The average crash rate from that study was 0.96 MEV.

There are no statewide crash rates calculated specifically for interchanges. Each interchange was analyzed separately and the results compared to other interchanges in the corridor and around the state. The data were compared to two other similar studies, the Wisconsin Backbone Needs and Improvement Study¹ and the Madison Beltline Operational Needs Assessment². Although the other studies are not identical in roadway type and traffic volumes, the comparison is valuable to show the relative crash rates at other interchanges studied in Wisconsin. **Table 2** summarizes the crash rate statistics for interchange influence areas.

¹ Wisconsin Backbone Needs and Improvement Study. EarthTech. 2007.

² Madison Beltline Operational Needs Assessment. HNTB Corporation. January 2008.

Table 2: Interchange Crash Rate Statistics

	Crash Rate				Crash Severity			
	Diverge	Merge	Weave	Terminal	Diverge	Merge	Weave	Terminal
Backbone Interchange Statistics								
Average	63	83	402	0.63	0.34	0.32	0.32	0.33
Average + 1SD	107	152	432	1.04	0.48	0.52	0.34	0.43
Madison Beltline Interchange Statistics								
Average	90	67	402	0.62	0.39	0.37	0.32	0.37
Average + 1SD	145	124	432	0.74	0.56	0.59	0.34	0.77
US 41 & WIS 441 Interchange Statistics								
Average	49	55	-	0.41	0.34	0.34	-	0.33
Average + 1SD	80	87	-	0.67	0.56	0.55	-	0.53

SD = Standard Deviation

- Diverge, merge, and weave crash rate units = 100 million vehicle miles traveled
- Terminal crash rate units = crashes per million entering vehicles

Overall, interchanges in the US 41 and WIS 441 corridor has a lower crash rate when compared to interchanges from previous studies. However, the crash severity is consistent with the other interchanges that were included in the statewide back bone study.

Exhibits C-1 through C-6 present the raw crash data.

1 – US 41 and Breezewood Lane

- Majority of crash types were ‘other’ and occurred in dry conditions
- The average annual crash rate is high for the SB on-ramp
- The crash severity is high for the SB off-ramp

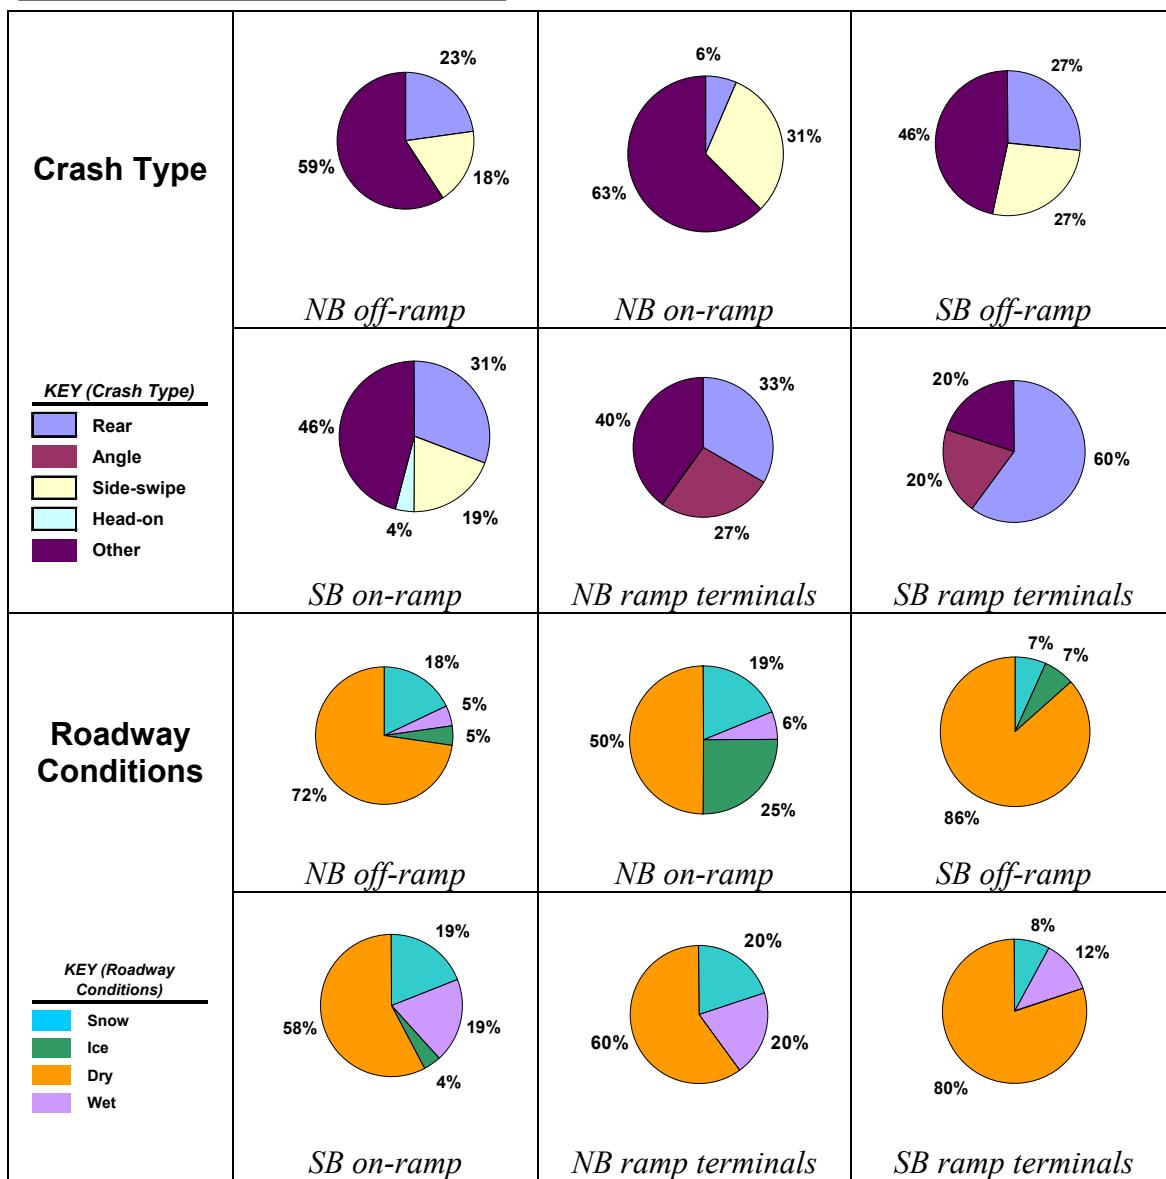

Exhibit C-6

18 – WIS 441 and CTH P (Racine Street)

- Majority of crash types were ‘other’ and occurred in dry conditions
- High crash rate for the southbound off-ramp and southbound loop on-ramp
- 43% of crashes at the southbound loop on-ramp occurred at night and 35% occurred on wet pavement

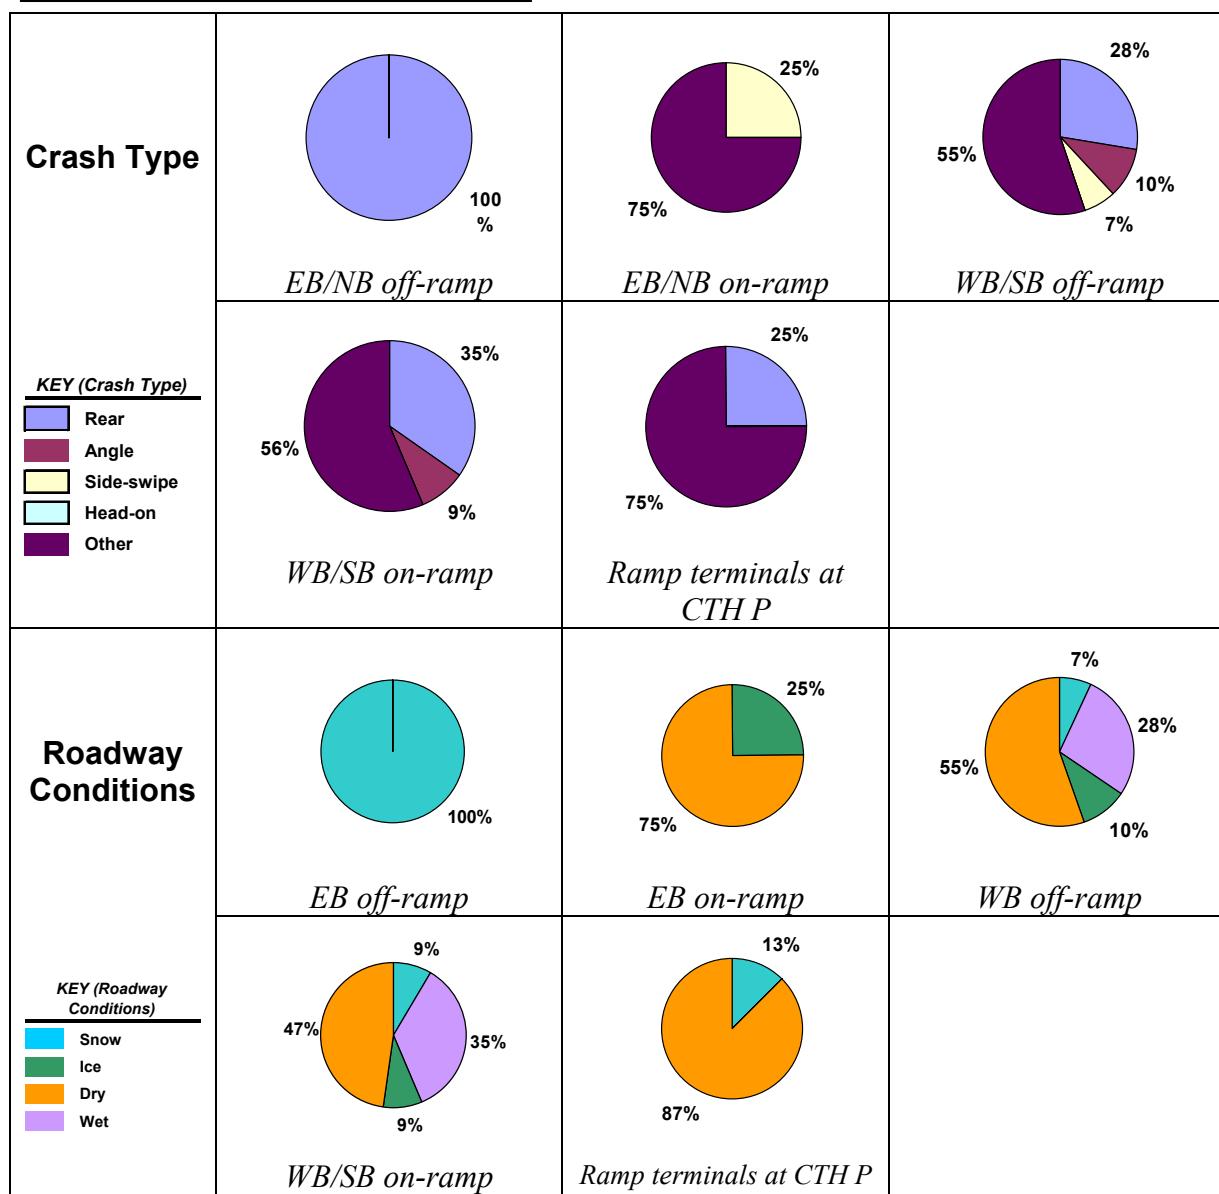

Exhibit C-6

24 – WIS 441 and CTH OO (Northland Avenue)

- High average annual crash rate on the southbound on-ramp
- 58% of crashes at the southbound ramp terminal were ‘angle crashes’
- The crash severity is high for the northbound on-ramp and the southbound off-ramp

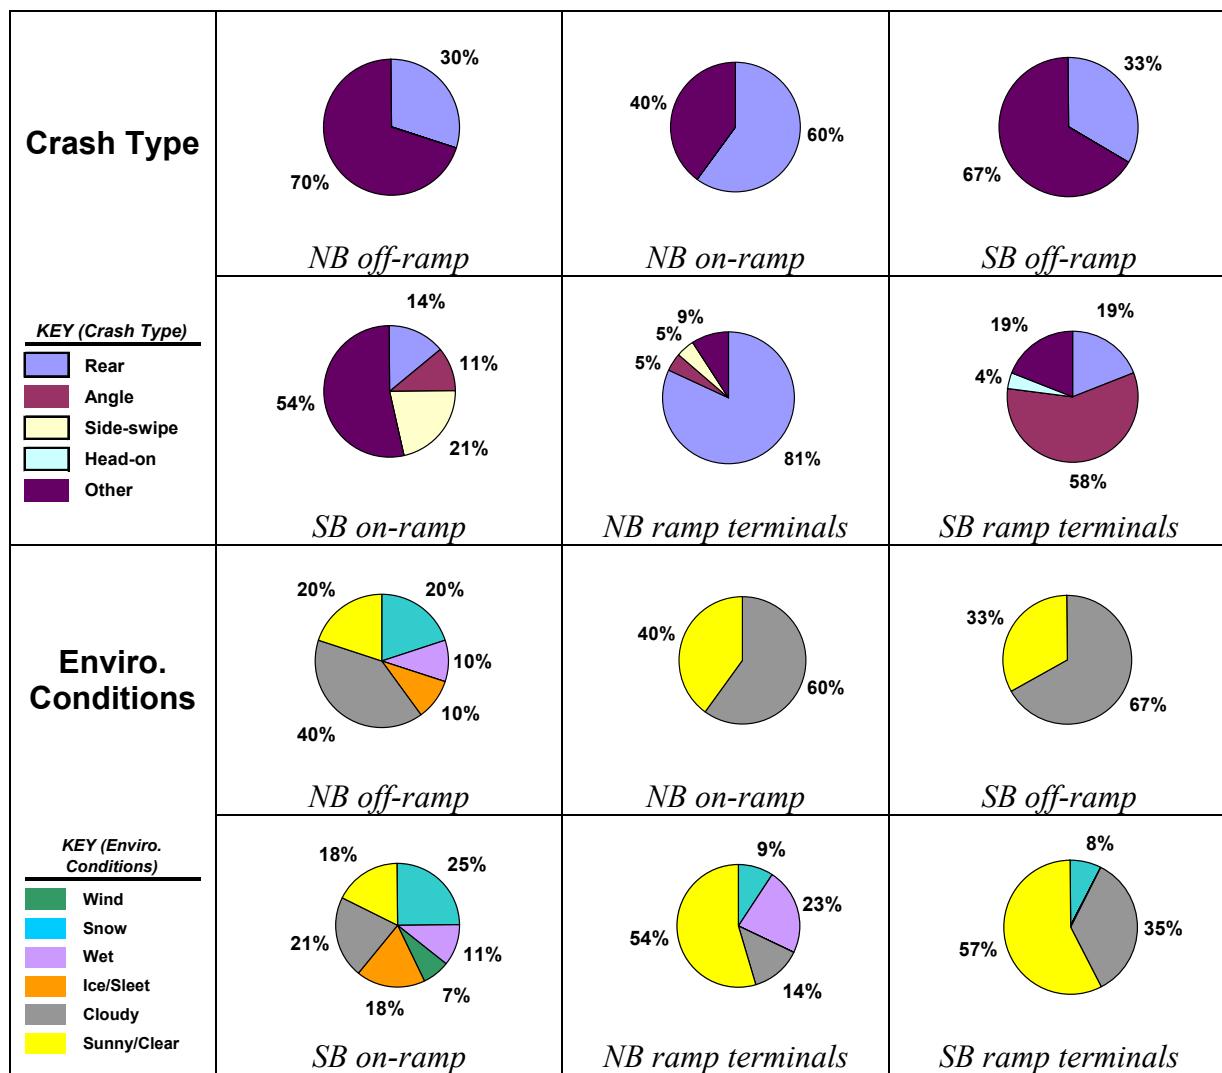

Exhibit C-6
